# Table of contents

## 01 Abstract

Short overview about key aspects of the system.

## 03 Code Analysis

Interpretation of code snippets about key aspects of the system.

## 02 In-depth view

Detailed description about the theory behind.

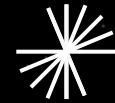

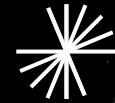

## 04

## Conclusions and future developments

Sorting about problems and possible developing route.

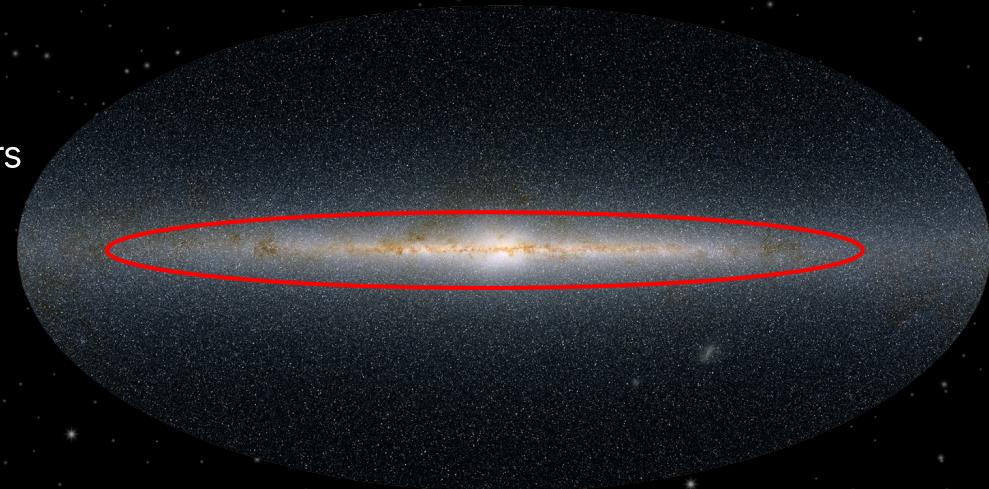

# 01

# Abstract

# Let's introduce the Zone of Avoidance

The **Zone of Avoidance**, or **Zone of Galactic Obscuration**, is an area in the galactic plane where dust, gas, and stars obstruct the view and sensors of the visible spectrum.

Circled in red, the Zone of Avoidance.

# Insufficient resources

Normally, **every** point of the galaxy must be **physically** studied, in order to discover new objects, because there are **very few** operative telescopes and astronomical sensors, compared to the vastity of the galaxy.

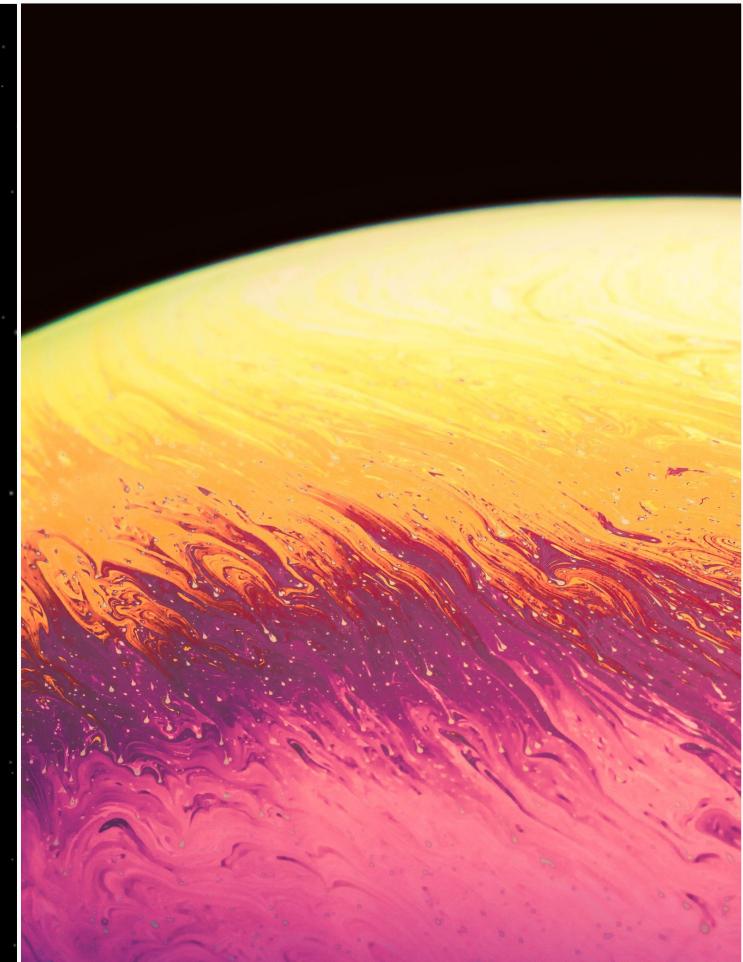

At least relatively to the theoretical number of **potential computers**.

# A smart contract to solve the problem

The system focuses on **overcoming** this obscuration, by **distributing analyses** of **incomplete** or **unprocessed** data gathered by astronomical sensor, **publicly** among machines, which will have the ability to choose and promote their **own perspective** and classification of celestial areas or bodies.

With such solution, entire space areas can be mapped with the **efficiency** for the astronomical sensor, physically studying only **sufficiently safe** space anomalies.

# The two fundamental actors

## Master node

Our *virtual* telescope and array of sensor, that **harvest astral datas** in the outer space and inject the smart contract with them.

Then it wait a proposal voted positively by the majority of peers, and if it turns empirically true, that proposal is saved, **certifying** a new discovery.

## Peer node

It is **whoever connects** itself to the smart contract, able to do **computations** to whatever is the meaning of the astral data extracted.

02

# In-depth view

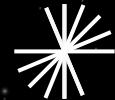

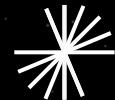

Unfortunately, an astrophysics lesson.

# Premise

Being a **one-man-army** project, it's very important to clarify that most theoretic concepts here are **overly simplified**, even **invented** by me, just for the sake of the project.

Nevertheless I will commit myself to highlight those **simplifications** and **fantasies**, as well as provide **references**.

# Use cases

Here are given **five<sup>[1]</sup>** examples of possible astral object: ***Rocky planet, Gas giant, Star, Supernova*** and ***Black hole***, each with their **unique values<sup>[2]</sup>** of ***mass, composition, temperature, difference of spectrum*** and ***microlensing magnitude***.

- The mass is calculated by the **Transit method**<sup>[1][1]</sup>, that occurs when the **light** of a space area **dimmer** at constant intervals.

Here the calculations are made by taking the **luminosity** of our star Sol

$$W_{\text{Sol}} = 3.827 \times 10^{26} \text{ W} \approx 4.0 \times 10^{26} \text{ W} = W^i_{\text{Sol}},$$

passed by the Earth

$$W^f_{\text{Sol}} = 4.0 \times 10^{25} \text{ W}.$$

So the **equation** will be

$$W^i_{\text{Sol}} - W^f_{\text{Sol}} = 3.6 \times 10^{26} \text{ W} = \Delta W_{\text{Sol-Earth}}.$$

Now with this simple **proportion**

$$\Delta W_{\text{Sol-Earth}} : \text{mass}_{\text{Earth}} = \Delta W_y : \text{mass}_x,$$

with  $\Delta W_y$  given by the astral data and  $\text{mass}_x$  variable, we can find the mass of **any** object.

- The *difference of spectrum* is a value gathered by **Spectroscopic**<sup>[2]</sup> sensors that will tell us if the body is a **star** or not, if it **fits** in that **range**<sup>[4]</sup> (typically from ultraviolet  $10^{-8}$  to radio  $10^3$ ).

- The *microlensing magnitude* is calculated using the **Gravitational microlensing method**<sup>[3]</sup>, which states that an object **passing** in front of another, will **bend** the fabric of space-time by **orders of magnitudes** relatively at its gravitational pull.  
Based on that, our sensors will gather that **magnitude**<sup>[5]</sup> of a locked point, after and before the passing of the space anomaly ( $M_i ; M_f$ ), guessing which **exotic body** it is.
- The *composition* is calculated by analyzing **three**<sup>[6]</sup> different radio wavelength measurement taken by the sensor, each corresponding with Hydrogen  $H = 21 \text{ cm}$ <sup>[4.1]</sup>, Helium  $He^{[4.2]} = 2.86 \text{ cm}$  and Silicium  $Si = 100 \text{ cm}^{[2]}$ .
- The *temperature* is calculated by the **Wien's displacement law**<sup>[5]</sup>, where harvested peaks of **infrared** wavelength can tell us the temperature of a body.

$$\lambda_{\text{peak}} = b / T, \text{ with } b = 2.898 \times 10^{-3} \text{ m/K as Wien constant.}$$

## Mass

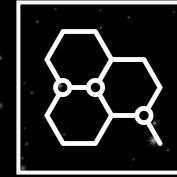

$\approx 0.1 \cdot mass_{Earth} \leq mass_x \leq 2 \cdot mass_{Earth}$

## Temperature

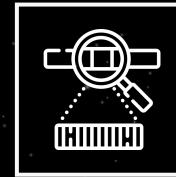

$\approx 123.15\text{ K} \leq T_x \leq 476.85\text{ K}$

# Rocky planet

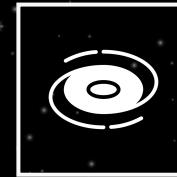

## Composition

**Must** have Si; can have H and He.

## Difference of spectrum

A rocky planet doesn't have it.

## Magnitude microlensing

A rocky planet doesn't have it.

# Gas Giant

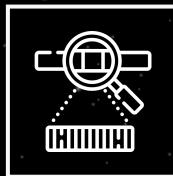

## Mass

$\approx 2 \cdot mass_{Earth} < mass_x \leq 0.1 \cdot mass_{Sol}$

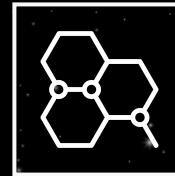

## Temperature

$\approx 123.15\text{ K} \leq T_x \leq 2500\text{ K}$

## Difference of spectrum

A gas giant doesn't have it.

## Composition

**Must not** have Si;  
H and He are **strongly** recommended.

## Magnitude microlensing

A gas giant doesn't have it.

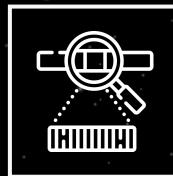

## Mass

$\approx 0.1 \cdot mass_{Sol} < mass_x \leq 10 \cdot mass_{Sol}$

## Temperature

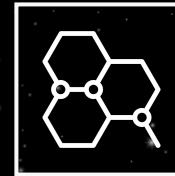

$\approx 2500 K < T_x \leq 50000 K$

## Difference of spectrum

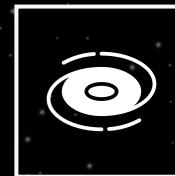

Border values similar to  $10^{-8}$  and  $10^3$ .

# Star

## Composition

**Must not** have *Si*;  
*H* and *He* are **strongly** recommended.

## Magnitude microlensing

A star doesn't have it.

## Mass

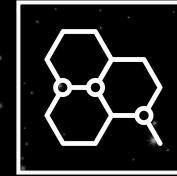

$\approx 10 \cdot mass_{Sol} < mass_x \leq 50 \cdot mass_{Sol}$

## Temperature

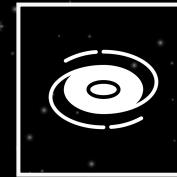

$\approx T_x > 50000 K$

# Supernova

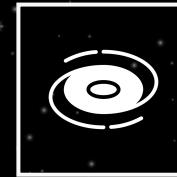

## Composition

**Absence** of  $H$ ,  $He$  and  $Si$   
strongly recommended.

## Difference of spectrum

A supernova doesn't have it.

## Magnitude microlensing

Difference must be slightly less.

## Mass

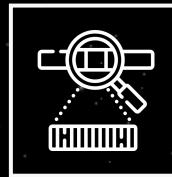

$\approx mass_x > 50 \cdot mass_{Sol}$

## Temperature

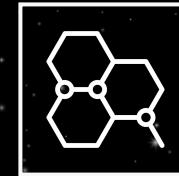

$\approx 2500 K < T_x \leq 50000 K$

# Black Hole

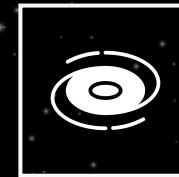

## Difference of spectrum

Border values similar to  $10^{-8}$  and  $10^3$ .

## Composition

**Absence** of  $H$ ,  $He$  and  $Si$   
strongly recommended.

## Magnitude microlensing

A star doesn't have it.

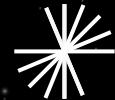

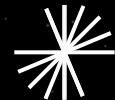

03

# Code Analysis

# Premise

The system is **fully working**, but, for now, only by **automated tests** runned by **JavaScript interfaces** to the smart contract, therefore there's **no human interaction** in the process to choose some data to analyze rather than another, **nor** the generated astral datas have some **physical meaning**, because it's all **pseudo-random generated**.

# Solidity contract

All informations are stored in **structs** like these...

```
struct Proposal {
    address proposer;
    uint dataID;
    astralObject object;
    int voteCount;
    bool isAccepted;
    mapping(address => bool) voters;
}
```

```
struct astralData{
    string id;
    int[] position;
    int Dw;
    int[] radioComposition;
    int lambda;
    int[] Ds;
    int[] magnitude;
}
```

```
struct astralObject{
    string id;
    int[] position;
    string tag;
    int T;
    bool[] composition;
    int mass;
}
```

# ...Through

pretty self-explanatory **functions** like these:

```
function addAstralData( ... ) public onlyAuthorized{  
    ...  
}
```

```
function addProposal( ... ) public{  
    ...  
}
```

```
function vote( ... ) public{  
    ...  
}
```

```
function markProposalAsAccepted( ... ) public onlyAuthorized{  
    ...  
}
```

# Deploying contract

The called constructor will set the **deployer address** as the authorized account or **master node**.

This means that functions and parts of the algorithm that have the **onlyAuthorized** keyword, can be *de facto* performed by only our master node.

```
constructor() {
    authorizedAccounts[msg.sender] = true;
    masterNode = msg.sender;
}

modifier onlyAuthorized() {
    require(authorizedAccounts[msg.sender], "Only authorized accounts can perform this action");
    _;
}
```

# JavaScript test

## Master node data creation

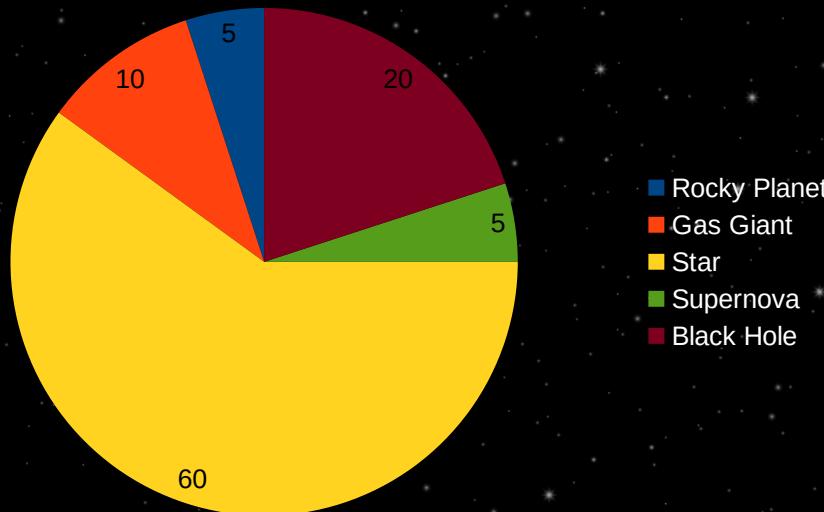

Starting with **masterNode.js**, the algorithm will *randomly* create **astral data** and inject them to smart contract, ready to be further analyzed.

```
async function createAstralData() {  
    //...  
}
```

Here, a dice will *roll* in order to simulate the **abundance** of certain types of astral object and the **scarcity** of others

```
var dice = getRandomNumber(0, 100);
```

Taking as example values of *lambda* for *rockyPlanet*,

```
var lambda = getRandomBigNumber(297231, 3361754)
```

These values are just the one that, **replaced** into the *Wien displacement law*, returns

$T = [123.15 \text{ K} ; 473.85 \text{ K}]$  (the **temperature limit** for *Rocky planets*), **enlarged** both ways by a 30%, and then **multiplied** by  $10^{10}$ .

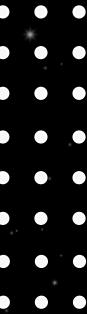

- The *multiplication* is made to ensure **compatibility** with **Solidity BigNumber**, because the language can't directly support decimal numbers, without some variables manipulation;
- The *enlargement* is introduced to achieve some sort of randomness, similar to the *dice roll*;
- Similar concept are made to the other critical variables, as well for other type of astral bodies,

Finally, those generated values are **injected** into the smart contract:

```
const accounts = await web3.eth.getAccounts();
const masterNode = accounts[0];
await contract.methods.addAstralData(id, position, Dw, radioComposition, lambda | 0, Ds, magnitude).send({ from: masterNode, gas: gasLimit });
```

First **two** lines, **fetch** the address of the *masterNode*/deployer, who will be the **first** [0] in the array of the accounts.

Then, an **asynchronous call** for the **addAstralData()** contract method will **create** a new variable within the smart contract, sent by the only authorized account.

## Peer node analysis and evaluation

About our *peerNode* algorithm, we have two separate \*js files:

***nodeLogic.js*** for the analysis of *astralData* and dispatching of a *proposal*.

A new proposal is prior created by *processing* and *analyzing* data, relatively at some ***reference values***.

```
function setReferenceValues(){
    refDw = BigNumber( getRandomBigNumber(BigNumber('3.3e26'), BigNumber('3.9e26')) );
    refT = +getRandomNumber(0, 0.15).toFixed(4);
    refComposition = [
        +getRandomNumber(0, 0.15).toFixed(4),
        +getRandomNumber(0, 0.15).toFixed(4),
        +getRandomNumber(0, 0.15).toFixed(4),
    ];
    refDspect = +getRandomNumber(0, 0.15).toFixed(4);
    refDmagnitude = Math.floor(getRandomNumber(2, 5));
    refThreshold = +getRandomNumber(0, 100).toFixed(2);
}
```

These values are unique for each node, as well as (in theory) tuneable.

- $\text{refDw}$  is the value of  $\Delta W_{\text{Sol-Earth}}$  stated by the *Transit method*. As previously mentioned,  $3.6 \times 10^{26}$  is the **median** values, but each node can pick a number between  **$3.3 \times 10^{26}$**  and  **$3.9 \times 10^{26}$** ;
- $\text{refT}$  is the **percentage** limit that can be tolerable for each astral body range of **temperature**;
- $\text{refComposition}$  is the **percentage** limit that can be tolerable for each astral body range of element **radio wavelength**;
- $\text{refDspect}$  is the **percentage** limit that can be tolerable for each astral body range of **spectrum**;
- $\text{refDMagnitude}$  set the **reference** for difference of order of **magnitude**;
- $\text{refThreshold}$  set the minimum *quality* a simulation must have to be dispatched as a proposal.

Subsequently, data are extracted at regular intervals...

```
async function extractAstralDatas(){
  //...
}
```

...then are *processed*...

```
async function processAstralDatas(extractAstralDatas){
  //...
}
```

...in order to further *analyze* the *critical values*.

```
async function analysisAstralDatas(processedData){
  //...
}
```

Following the previous example of *lambda*, it's important to note that the value is correctly divided by  $10^{10}$ , ensuring the correct computation of the law.

```
T = (wienConstant.dividedBy(BigNumber(extractedAstralDatas[c].lambda).dividedBy('10e10')));
```

Again, I point out that values are manipulated in order to do calculations and be *Solidity-compatible*.

- Inside `analysisAstralData()` function, checks about *critical values* are made, relatively at *reference values* and the standard *critical unique values* for each type of astral body, that will update the corresponding **score**.

Here are stored the scores of each guess...

```
objectGuess = [0, 0, 0, 0, 0];
```

...updated by checks like this...

```
if(processedData.mass.isGreater Than(rockyPlanet.rMass[0]) && processedData.mass.isLessThanOrEqualTo(rockyPlanet.rMass[1])){
    objectGuess[0] += 40;
    objectGuess[1] -= 10;
    objectGuess[2] -= 20;
    objectGuess[3] -= 30;
    objectGuess[4] -= 40;
}
```

Positive for *mass* in range of *rockyPlanet*

Then, if a score is equal or greater than the *refThreshold*, a new proposal is assembled and dispatched, with the data of the guessed *astralObject*.

About ***nodeEvaluationLogic.js***, the algorithm is still pretty the same: the node **extract** the proposal from the pool, then proceed to make the same **computations** of *nodeLogic.js*, and if the result is tolerable, that proposal is **voted** positively, else negatively.

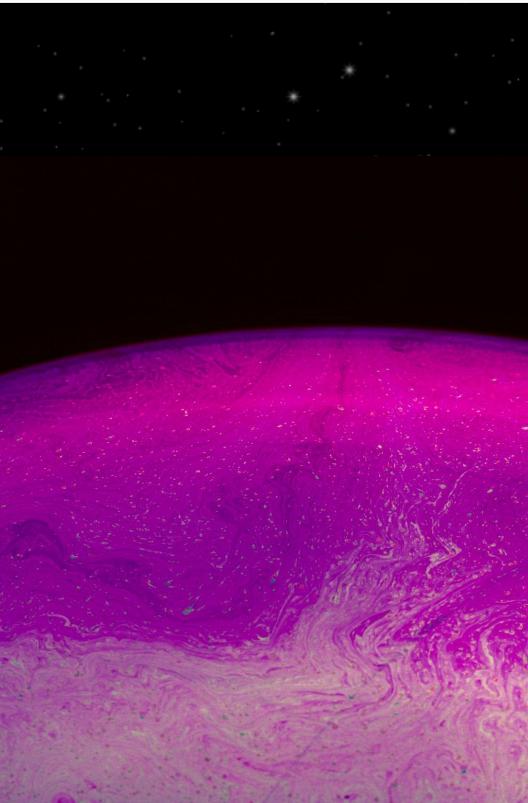

```
// If the analyzed proposal return a reasonable guess, then a positive vote will be dispatched
console.log("This is a good guess! Voting for... ", processedData.id);
votedPoV = processedData.id
vote = 1;
voteProposal(votedPoV, vote);
}
else{
    // If the analyzed proposal return a bad guess, then a negative vote will be dispatched
    console.error("This is a bad guess. Voting against... ", processedData.id);
    votedPoV = processedData.id
    vote = -1;
    voteProposal(votedPoV, vote);
    tag = "unknown";
}
}
```

## Master node validation

The algorithm ***masterNodeValidation.js*** remains pretty similar to the ones concerning peer nodes: here, proposal voted positively by the majority are **empirically** studied, and if the guess turns out **acceptably** true, that proposal are marked as **accepted**, meaning that a new astral body is discovered and his spotter is **certificated**.

```
//...
console.log("This is a good guess! We Have WINNER! ", processedData.proposalID);
acceptedPoV = processedData.proposalID;
acceptProposal(acceptedPoV);
}
//...
```

Case of a positive guess

# 04

# Conclusions

# Problems

Alas, the system is not exempt of theoretic, logical and efficiency failures:

- **Theory:**
  - Concepts are overly **simplified**, **insufficient** and even **invented**;
  - Very **few** use cases and **inadequate** *critical unique values*.
- **Coding:**
  - **No human interaction** is possible;
  - *Master node* generate **meaningless** data and uses the **same logic** of a peer to validate the proposal;
  - **Only two** peer nodes available.
  - If there are too much *astralData* in the contract, the **system saturate**, sensibly slowing the machine;
  - **Bad efficiency** in some segments of the code.

# Solution

Like most everything, improvements can be made:

- **Theory:**
  - Extend and scientifically verify the concepts;
  - Expand use cases and *critical unique values*.
- **Coding:**
  - *Master node* algorithm only as interface to the contract for the telescopes/sensors, implying no calculation about the proposal, because there will be physical check;
  - Add the ability to publicly connect anyone who wants it, through an interactive web page/app;
  - (?) Save and retrieve *astralData* not directly within the smart contract, but through transaction receipts;
  - Study and deploy new methods to achieve better performance.

# Web interface mockup

**SCAO**

Smart Contract Astral Object

**Overview**

Smart Contract Astral Object, or SCAO, is a fully independent developed smart contract for Ethereum that try to collimate the galactic space shadowed by the "Zone of Avoidance".  
The Zone of Avoidance, or Zone of Galactic Obscuration, is an area in the galactic plane where dust, gas, and stars obstruct the view and sensors of the visible spectrum.

Taking deliberate inspiration from the experiences of Foldit and SETI@home, the project focuses on developing a system capable of overcoming this obscuration by distributing analyses publicly among machines, which will have the ability to choose and promote their own perspective and classification of celestial areas or bodies. More specifically, all peer nodes can propose a point of view/PoV based on pre-existing astronomical data (as well as data validated subsequently within the blockchain), their own simulations, and assumptions. This viewpoint will be validated by the majority of the remaining peers if they consider it acceptable according to their parameters. At the end of the negotiation, virtual telescopes and astronomical sensors will point in the indicated direction, and if the simulation proves to be true, the proposal of the winning peer will be inserted into the blockchain, along with its identifier.

Thus, the computational part of SETI@home is carried forward, as well as the "puzzle" aspect of Foldit, along with distributed assistance for research.

**START**

The screenshot shows a web browser window with a dark blue header bar. In the top right corner of the header are three small red icons: a yellow minus sign, a blue square, and a red asterisk. The main title "SCAO" is displayed in large white letters. To the right of the title is a "Login" button and a white horizontal menu icon consisting of three vertical bars. Below the title, the subtitle "Smart Contract Astral Object" is shown in a smaller white font. The main content area has a white background and features a large, bold, black "Overview" heading. Underneath it, there are two sections of text in black font. The first section discusses the "Zone of Avoidance" and its relation to the "Zone of Obscuration". The second section provides a detailed explanation of the project's methodology, mentioning "Foldit" and "SETI@home" as inspirations, and describes how peer nodes propose viewpoints and validate them through simulations and astronomical data. At the bottom of the content area is a large blue rectangular button with the word "START" in white capital letters.

# Overview

Smart Contract Astral Object

## Overview

Smart Contract Astral Object, or SCAO, is a fully decentralized system for the creation of astronomical objects.

The Zone of Avoidance, or Zone of Galactic Concentration, is the volume of space

Taking deliberate inspiration from the experience of Foldit, SCAO is designed to be capable of overcoming this obscuration by allowing users to propose their own perspective and choose and promote their own perspective and propose a point of view/PoV based on pre-existing data (e.g., data from the blockchain), their own simulations, and assumptions.

If they consider it acceptable according to the rules of the game, other astronomical sensors will point in the indicated direction and the peer will be informed.

Thus, the computational part of SETI@home is
